Mitacs

The Algae-WISE project

Mobilisation

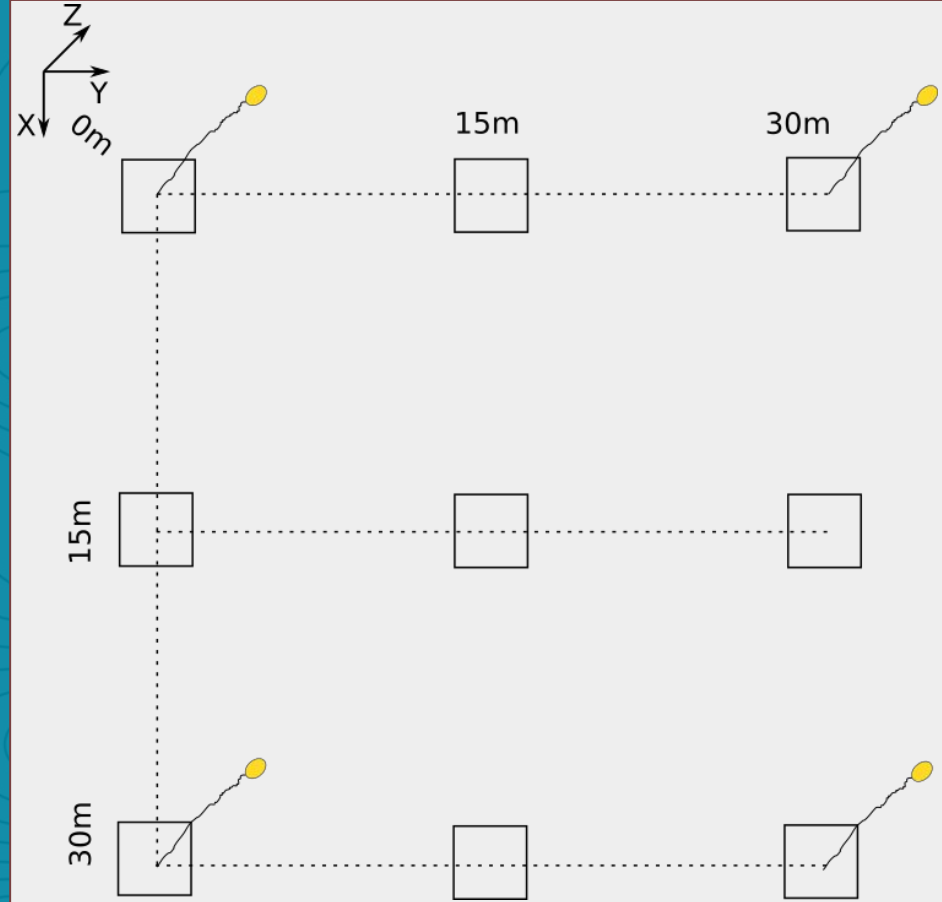

- NRC FLR Plane
- Coriolis 2
- Diving team
- Jet-ski

Ground-truth sampling plan

- Macroalgal cover harvested in 9 quadrats
- 0.25 m² quadrat
- Surface buoy deployed in corner for georeferencing

Ground-truth diving sites

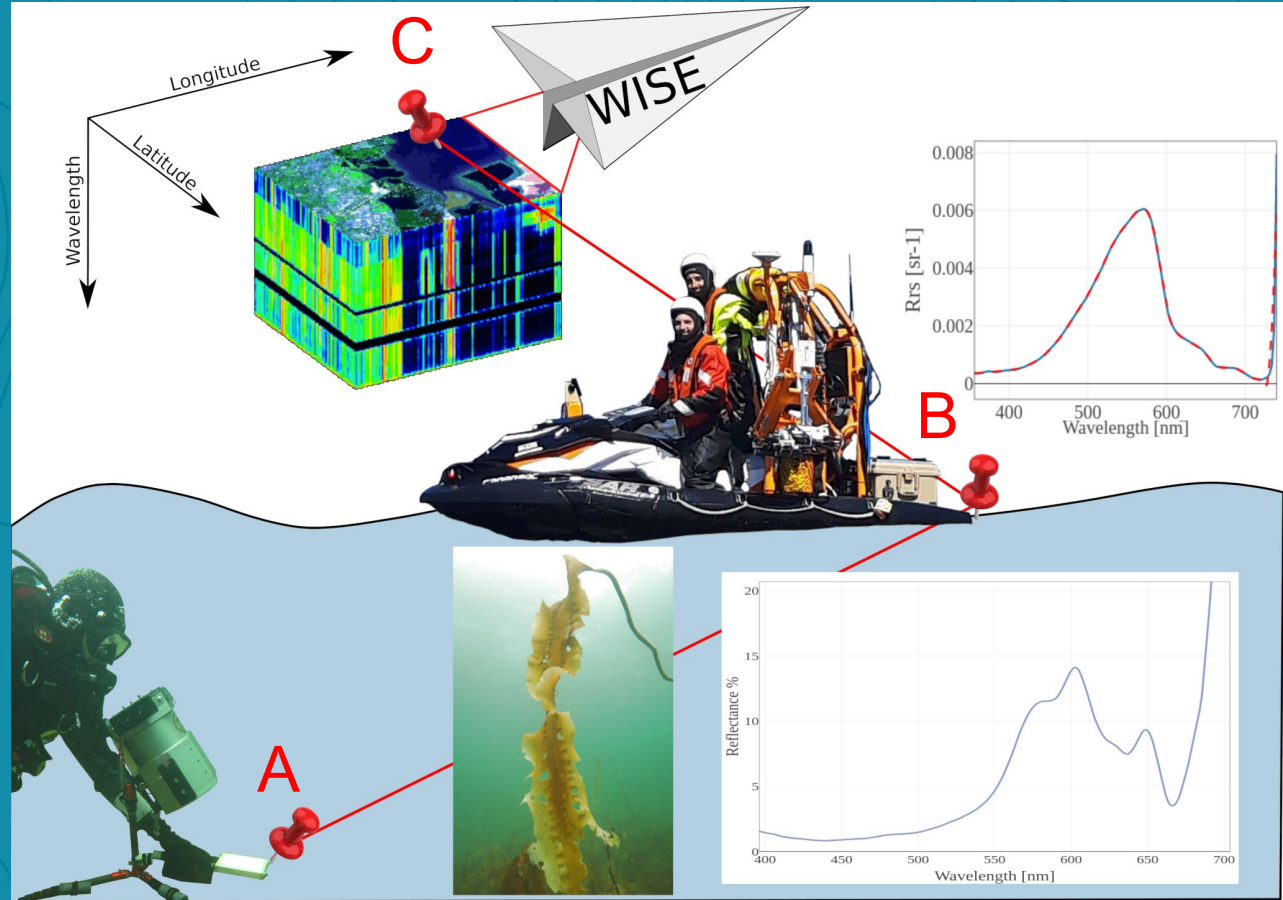

- Purple point: corner of sampling grid
- 9 diving sites
- Measurement:
 - Species
 - Density
 - Biomas
- 1 underwater hyperspectral radiometry transect

Concept

- Three hyperspectral acquisitions

A jet-ski as an acquisition platform

Acquire data up to
~ two meters depth

Combine acoustic
and optical
instruments

Continuous
acquisition

Instruments

→ GPS RTK
Lat, Lon,
Altitude, DateTime

→ HOCR
Incident light
above water

→ CTD, pH, DO

Instruments

→ HOCR
Upwelling light at
two different
depths

→ Depth,
Canopy Height

→ Backscattering,
Chl-a, FDOM

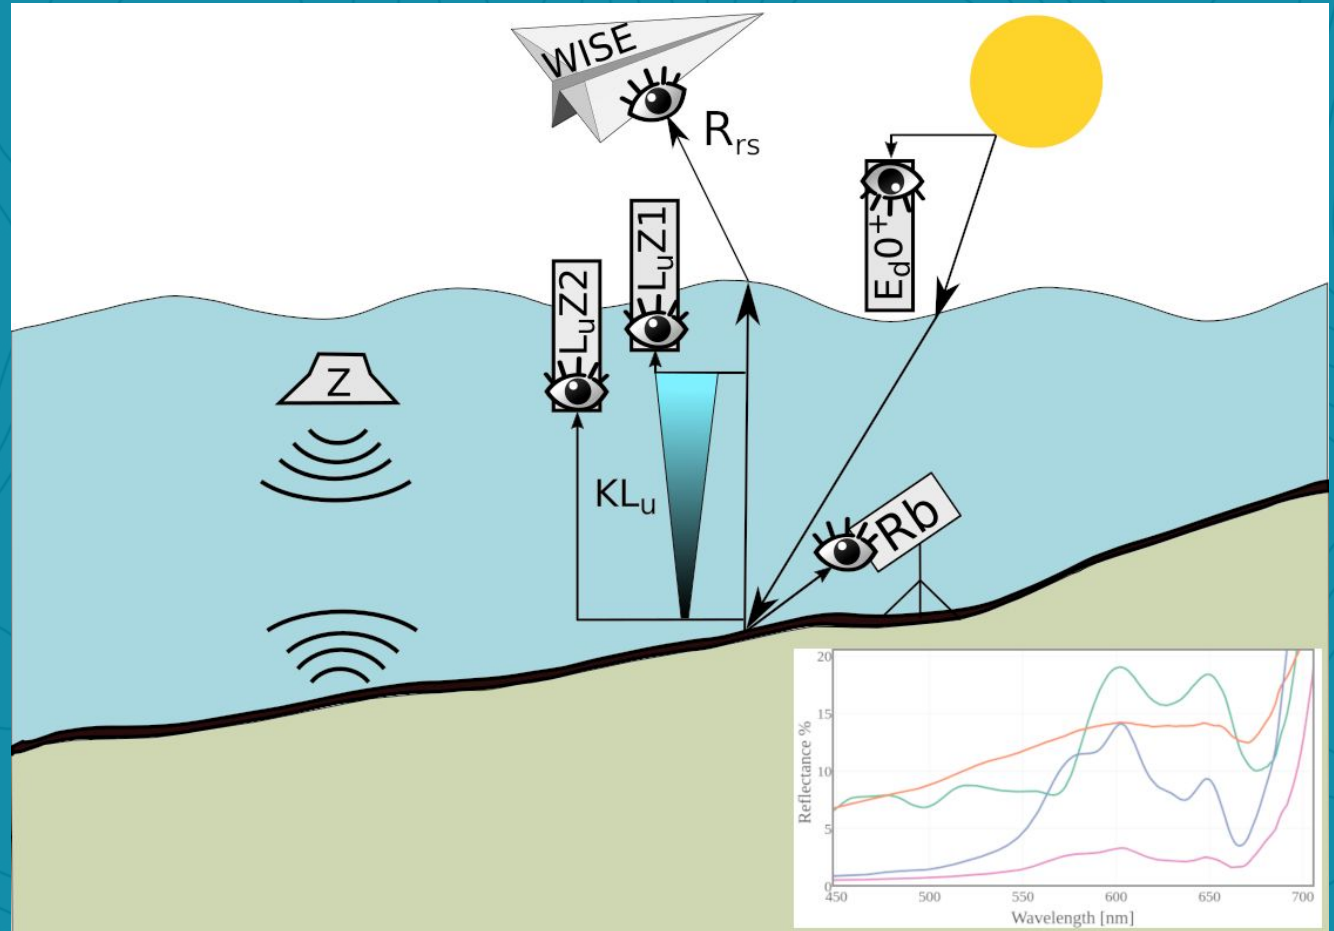

→ Turbidity,
Pigments

→ Depth

Objectives

1. Retrieve aquatic reflectance (R_{rs})
2. Combine optical and acoustic sensors (Z , KL_u)
3. Retrieve benthic reflectance (R_b)

Overview

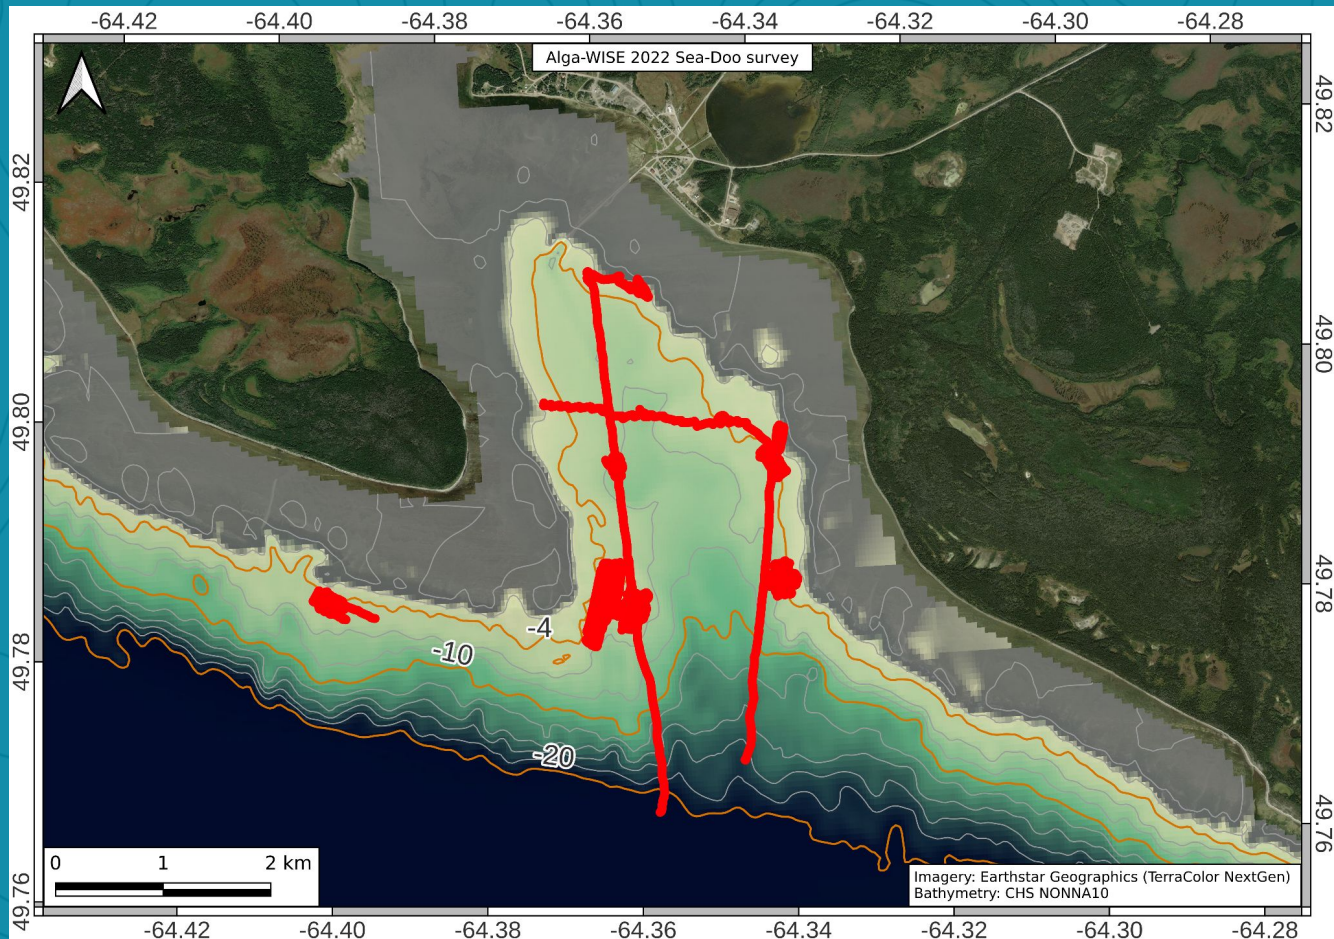

51 514 seconds
~ 14.31
survey hours

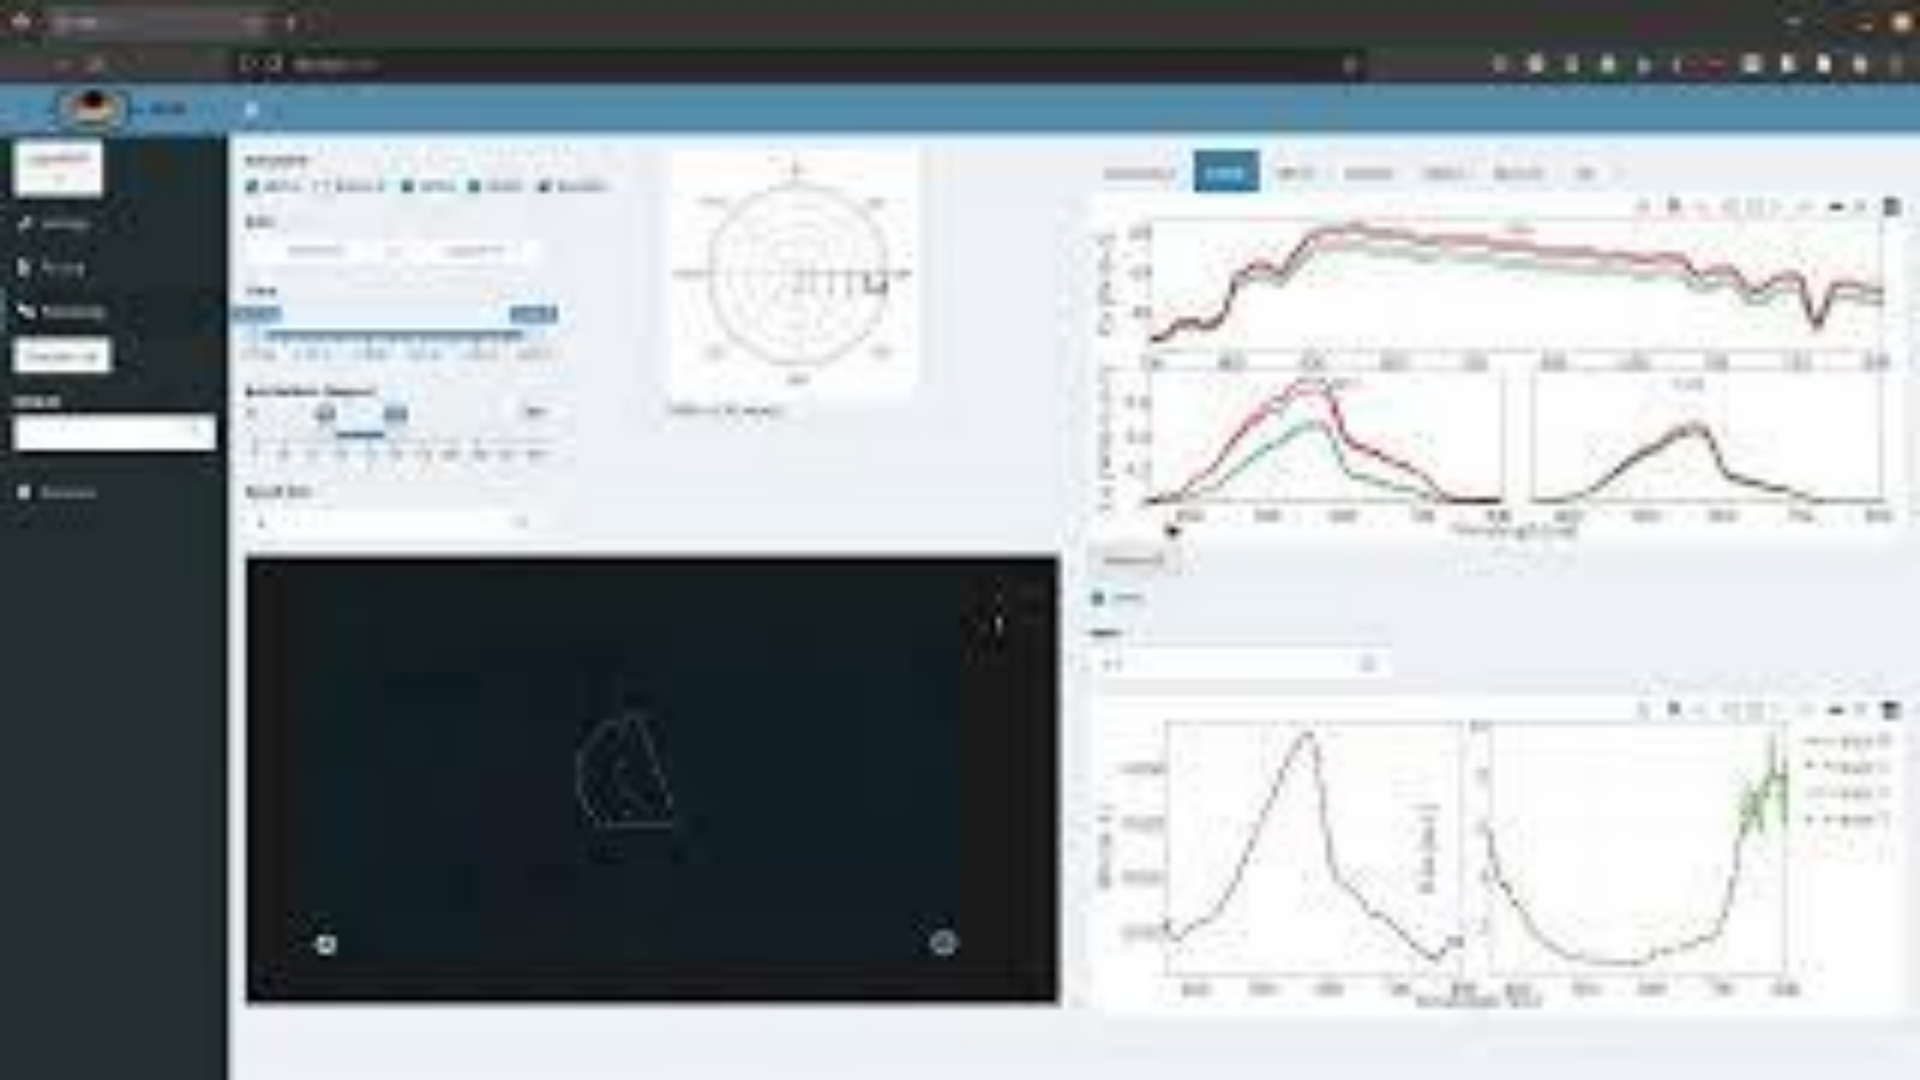

~ 5 seconds to
discretize an
observation

~ 10 302 discretized
observations

~ 5 minutes to
process one
observation

~ 858 hours of
processing

Optic and acoustic combination

1. Aquatic reflectance: R_{rs}

2. Attenuation coefficient: KL_u

Optic and acoustic combination

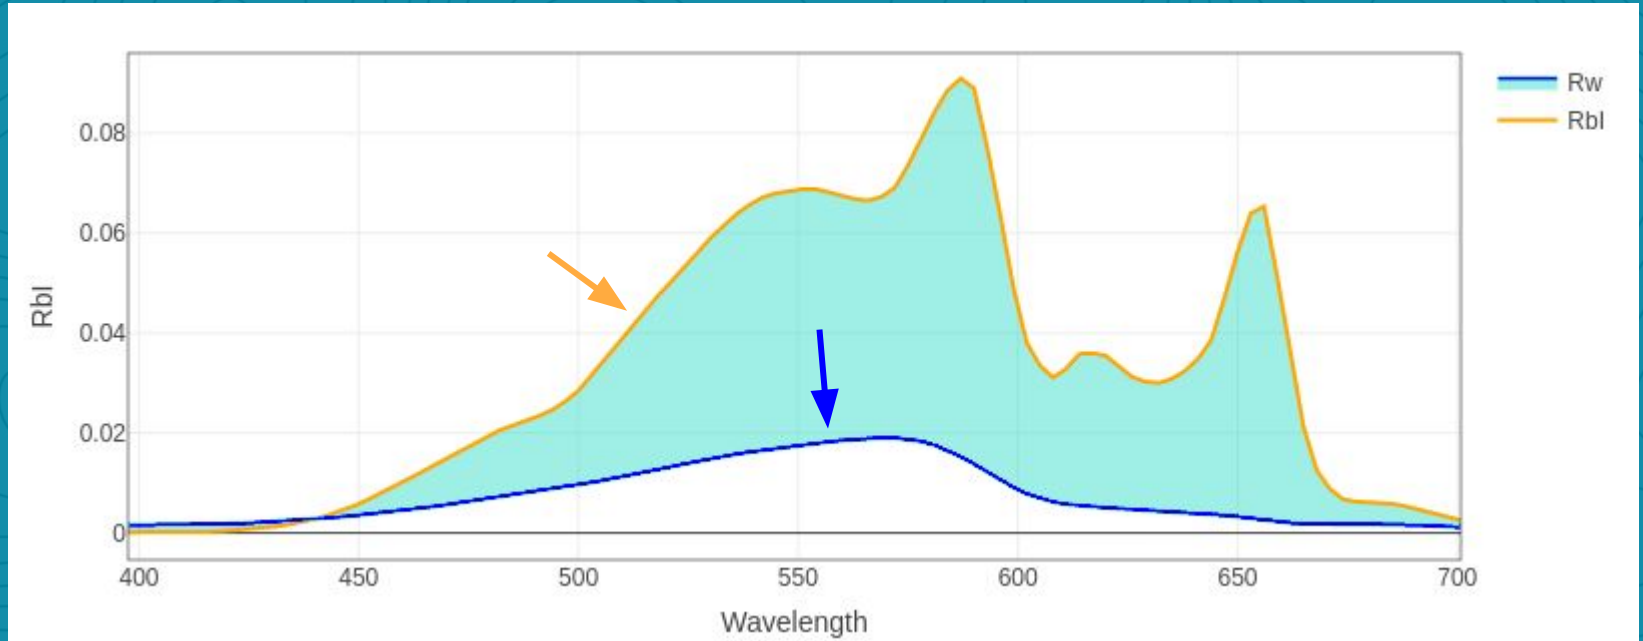

3. Water depth above **bottom** (-4.50 m) or **algal canopy** (0.71 m) : Z

4. We can estimate the **bottom reflectance** by removing the **water column contribution** from the **total signal** :

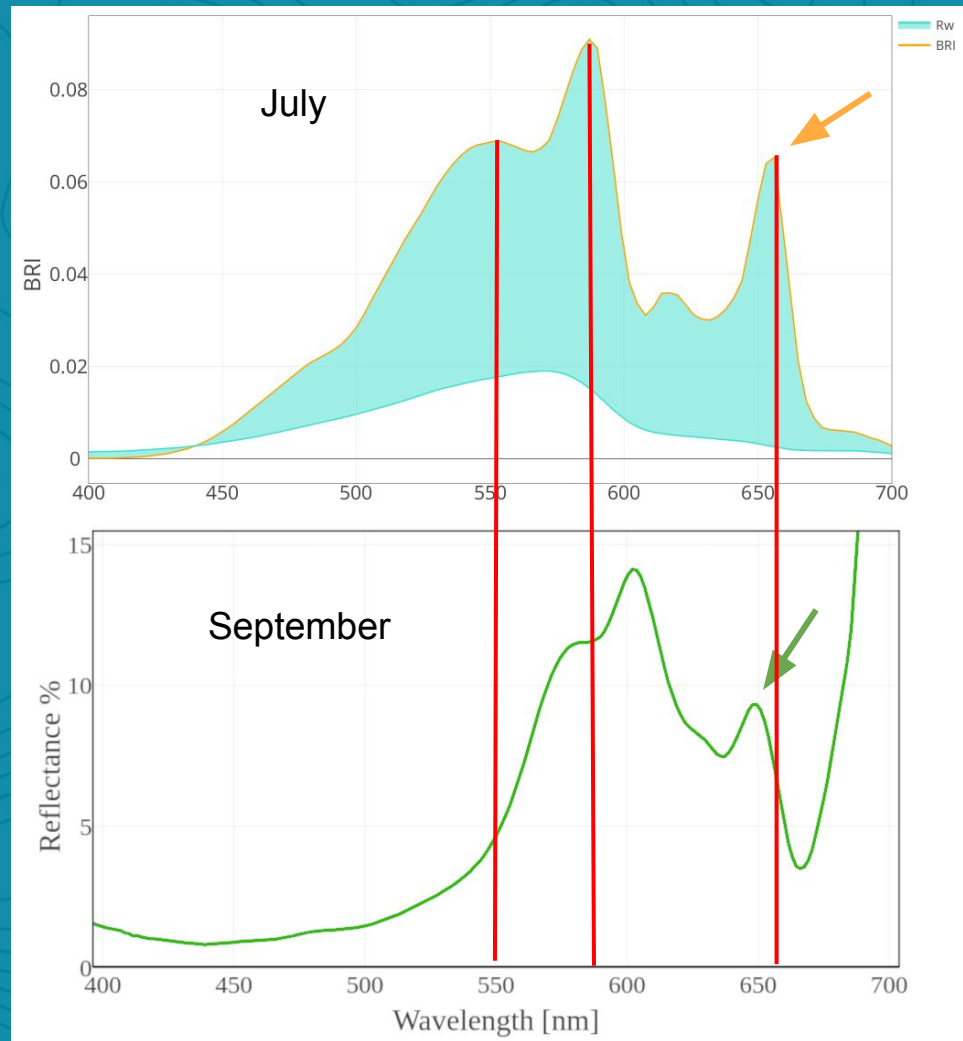

$$\rho_b = \rho_w - \rho_{wc}$$

$$\rho_b = \pi \cdot R_{rs} / e^{(-KL_u \cdot Z)}$$

Spectral signature

- Estimated **benthic reflectance** closely match the **spectral shape of kelp**
- Difference in peak reflectance related to seasonality ?

Hydrospatial perspectives

- "Big data" for AI algorithm development
- Automated detection of macroalgae
- Worldwide daily imagery at ~4m resolution
- Study spatio-temporal change

Thank You !
